

GENERAL DESCRIPTION

The XRT83VL38 is a fully integrated Octal (eight channel) long-haul and short-haul line interface unit for T1 (1.544Mbps) 100Ω, E1 (2.048Mbps) 75Ω or 120Ω, J1 110Ω or BITS Timing applications.

In long-haul applications the XRT83VL38 accepts signals that have been attenuated from 0 to 36dB at 772kHz in T1 mode (equivalent of 0 to 6000 feet of cable loss) or 0 to 43dB at 1024kHz in E1 mode.

In T1 applications, the XRT83VL38 can generate five transmit pulse shapes to meet the short-haul Digital Cross-Connect (DSX-1) template requirements as well as for Channel Service Units (CSU) Line Build Out (LBO) filters of 0dB, -7.5dB -15dB and -22.5dB as required by FCC rules. It also provides programmable transmit pulse generators for each channel that can be used for output pulse shaping allowing performance improvement over a wide variety of conditions (The arbitrary pulse generators are available in both T1 and E1 modes).

The XRT83VL38 provides both a parallel/serial Host microprocessor interface as well as a Hardware mode for programming and control.

Both the B8ZS and HDB3 encoding and decoding functions are selectable as well as AMI. Two on-chip

crystal-less jitter attenuators with a 32 or 64 bit FIFO can be placed in the receive and the transmit paths with loop bandwidths of less than 3Hz. The XRT83VL38 provides a variety of loop-back and diagnostic features as well as transmit driver short circuit detection and receive loss of signal monitoring. It supports internal impedance matching for 75Ω, 100Ω, 110Ω and 120Ω for both transmitter and receiver. In the absence of the power supply, the transmit outputs and receive inputs are tri-stated allowing for redundancy applications. The chip includes an integrated programmable clock multiplier that can synthesize T1 or E1 master.

APPLICATIONS

- BITS Timing
- T1 Digital Cross-Connects (DSX-1)
- ISDN Primary Rate Interface
- CSU/DSU E1/T1/J1 Interface
- T1/E1/J1 LAN/WAN Routers
- Public switching Systems and PBX Interfaces
- T1/E1/J1 Multiplexer and Channel Banks

Features (See Page 2)

FIGURE 1. BLOCK DIAGRAM OF THE XRT83VL38 T1/E1/J1 LIU (HOST MODE)

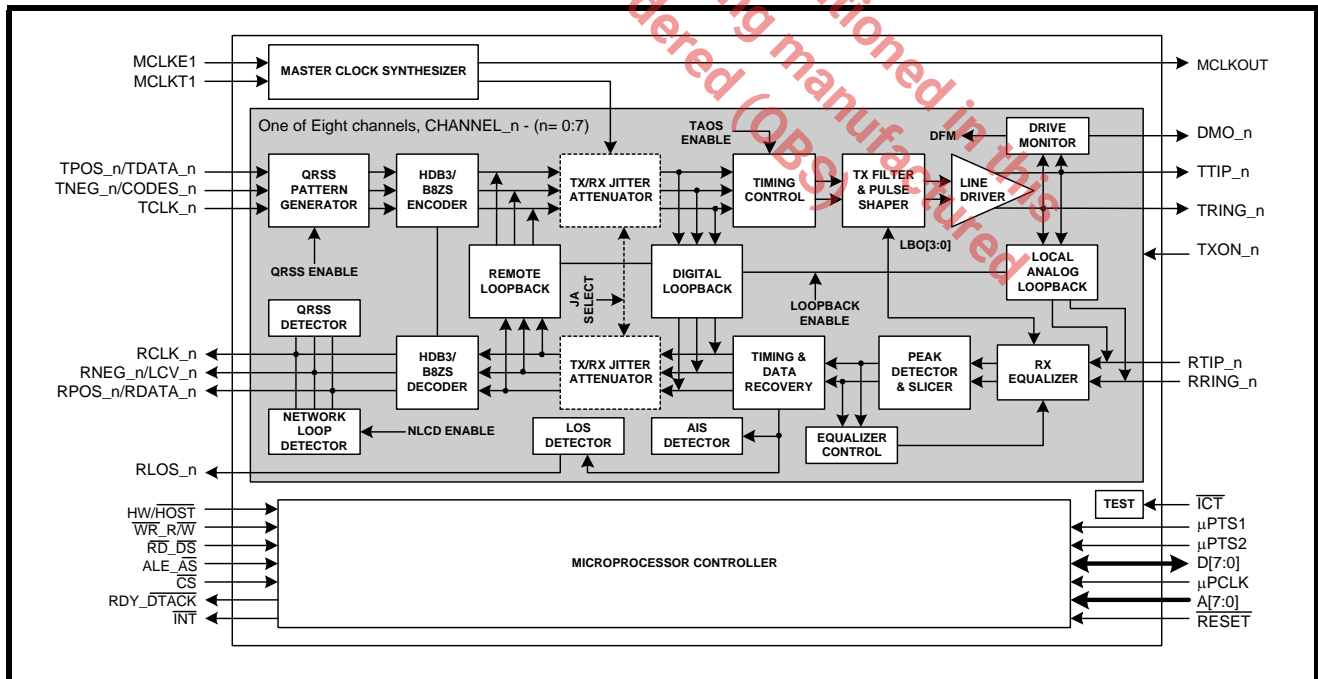

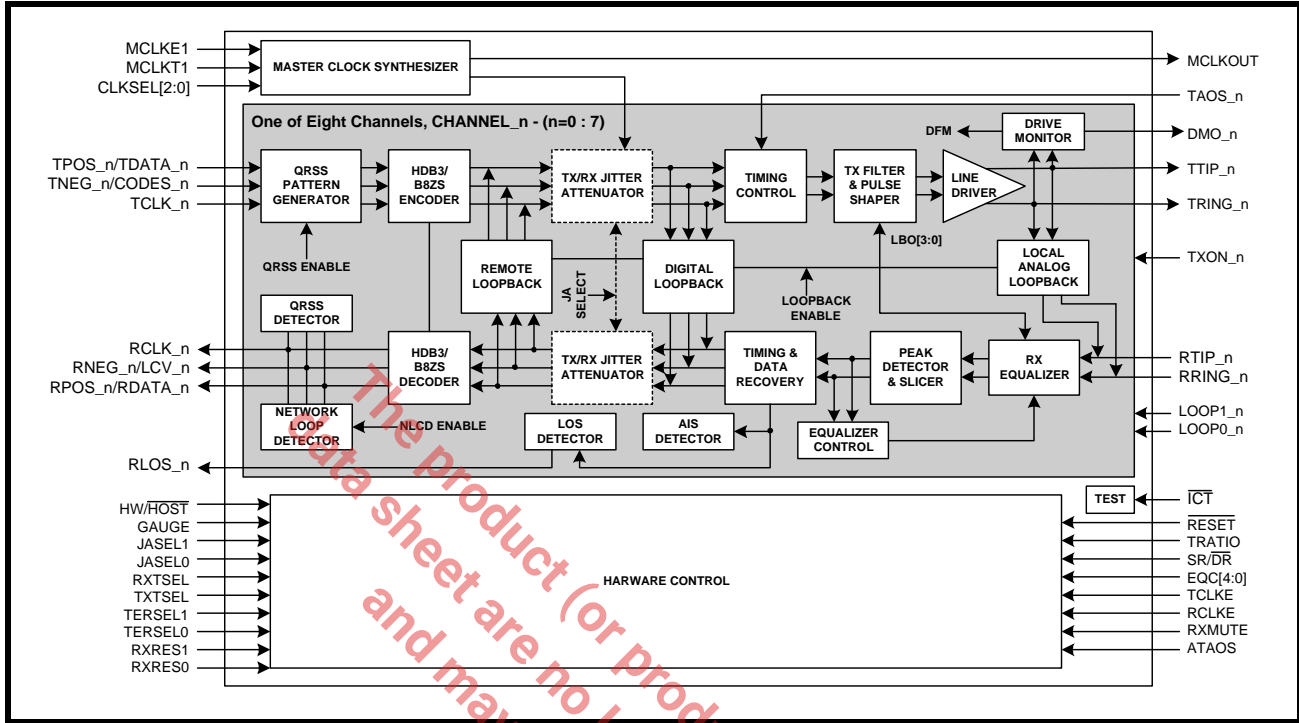

FIGURE 2. BLOCK DIAGRAM OF THE XRT83VL38 T1/E1/J1 LIU (HARDWARE MODE)

FEATURES

- Supports Section 13 - Synchronization Interface in ITU G.703 for both Transmit and Receive Paths
- Fully integrated eight channel long-haul or short-haul transceivers for E1,T1 or J1 applications
- Adaptive Receive Equalizer for up to 36dB cable attenuation
- Programmable Transmit Pulse Shaper for E1,T1 or J1 short-haul interfaces
- Five fixed transmit pulse settings for T1 short-haul applications plus a fully programmable waveform generator for transmit output pulse shaping available for both T1 and E1 modes
- Transmit Line Build-Outs (LBO) for T1 long-haul application from 0dB to -22.5dB in three 7.5dB steps
- Selectable receiver sensitivity from 0 to 36dB cable loss for T1 @772kHz and 0 to 43dB for E1 @1024kHz
- Receive monitor mode handles 0 to 29dB resistive attenuation along with 0 to 6dB of cable attenuation for E1 and 0 to 3dB of cable attenuation for T1 modes
- Supports 75Ω and 120Ω (E1), 100Ω (T1) and 110Ω (J1) applications
- Internal and/or external impedance matching for 75Ω, 100Ω, 110Ω and 120Ω
- Tri-State transmit output and receive input capability for redundancy applications
- Provides High Impedance for Tx and Rx during power off
- Transmit return loss meets or exceeds ETSI 300-166 standard
- On-chip digital clock recovery circuit for high input jitter tolerance
- Crystal-less digital jitter attenuator with 32-bit or 64-bit FIFO selectable in transmit or receive paths
- On-chip frequency multiplier generates T1 or E1 Master clocks
- High receiver interference immunity
- On-chip transmit short-circuit protection and limiting, and driver fail monitor output (DMO)

- Receive loss of signal (RLOS) output
- On-chip HDB3/B8ZS/AMI encoder/decoder functions
- QRSS pattern generator and detection for testing and monitoring
- Error and Bipolar Violation Insertion and Detection
- Receiver Line Attenuation Indication Output in 1dB steps
- Network Loop-Code Detection for automatic Loop-Back Activation/Deactivation
- Transmit All Ones (TAOS) and In-Band Network Loop Up and Down code generators
- Supports Local Analog, Remote, Digital and Dual Loop-Back Modes
- Meets or exceeds T1 and E1 short-haul and long-haul network access specifications in ITU G.703, G.775, G.736 and G.823; TR-TSY-000499; ANSI T1.403 and T1.408; ETSI 300-166 and AT&T Pub 62411
- Supports both **Hardware** and **Host** (parallel or serial) Microprocessor interface for programming
- Programmable Interrupt
- Low power dissipation
- Logic inputs accept either 3.3V or 5V levels
- Dual 3.3V and 1.8V Supply Operation
- 225 ball BGA package
- -40°C to +85°C Temperature Range

PIN DESCRIPTION BY FUNCTION

RECEIVE SECTIONS

SIGNAL NAME	LEAD #	TYPE	DESCRIPTION
RxON	K16	I	Receiver On - Hardware Mode Writing a "1" to this pin in Hardware mode turns on the Receive Sections of all channels. Writing a "0" shuts off the Receiver Sections of all channels.
RLOS_0	C3	O	Receiver Loss of Signal for Channel_0: This output signal goes "High" for at least one RCLK_0 cycle to indicate loss of signal at the receive 0 input. RLOS will remain "High" for the entire duration of the Loss of Signal detected by the receiver logic. SEE "RECEIVER LOSS OF SIGNAL (RLOS)" ON PAGE 25.
RLOS_1	H4		Receiver Loss of Signal for Channel_1
RLOS_2	H15		Receiver Loss of Signal for Channel_2
RLOS_3	A16		Receiver Loss of Signal for Channel_3
RLOS_4	V3		Receiver Loss of Signal for Channel_4
RLOS_5	L2		Receiver Loss of Signal for Channel_5
RLOS_6	J15		Receiver Loss of Signal for Channel_6
RLOS_7	T15		Receiver Loss of Signal for Channel_7
RCLK_0	B3	O	Receiver Clock Output for Channel_0
RCLK_1	H3		Receiver Clock Output for Channel_1
RCLK_2	H16		Receiver Clock Output for Channel_2
RCLK_3	A17		Receiver Clock Output for Channel_3
RCLK_4	U3		Receiver Clock Output for Channel_4
RCLK_5	L3		Receiver Clock Output for Channel_5
RCLK_6	M15		Receiver Clock Output for Channel_6
RCLK_7	U16		Receiver Clock Output for Channel_7
RNEG_0	A2	O	Receiver Negative Data Output for Channel_0 - Dual-Rail mode This signal is the receive negative-rail output data.
LCV_0	A2		Line Code Violation Output for Channel_0 - Single-Rail mode This signal goes "High" for one RCLK_0 cycle to indicate a code violation is detected in the received data of Channel_0. If AMI coding is selected, every bipolar violation received will cause this pin to go "High".
RNEG_1	H2		Receiver Negative Data Output for Channel_1
LCV_1			Line Code Violation Output for Channel_1
RNEG_2	H18		Receiver Negative Data Output for Channel_2
LCV_2			Line Code Violation Output for Channel_2
RNEG_3	B16		Receiver Negative Data Output for Channel_3
LCV_3			Line Code Violation Output for Channel_3
RNEG_4	T4		Receiver Negative Data Output for Channel_4
LCV_4			Line Code Violation Output for Channel_4
RNEG_5	M4		Receiver Negative Data Output for Channel_5
LCV_5			Line Code Violation Output for Channel_5
RNEG_6	M16		Receiver Negative Data Output for Channel_6
LCV_6			Line Code Violation Output for Channel_6
RNEG_7	V17		Receiver Negative Data Output for Channel_7
LCV_7			Line Code Violation Output for Channel_7

SIGNAL NAME	LEAD #	TYPE	DESCRIPTION
RPOS_0	B2	O	Receiver Positive Data Output for Channel _0 - Dual-Rail mode This signal is the receive positive-rail output data sent to the Framer.
RDATA_0	B2		Receiver NRZ Data Output for Channel _0 - Single-Rail mode This signal is the receive output data.
RPOS_1	G2		Receiver Positive Data Output for Channel _1
RDATA_1			Receiver NRZ Data Output for Channel _1
RPOS_2	D15		Receiver Positive Data Output for Channel _2
RDATA_2			Receiver NRZ Data Output for Channel _2

FUNCTIONAL DESCRIPTION

The XRT83VL38 is a fully integrated long-haul and short-haul transceiver intended for T1, J1 or E1 systems. Simplified block diagrams of the chip are shown in **Figure 1, Host mode** and **Figure 2, Hardware mode**. The XRT83VL38 can receive signals that have been attenuated from 0 to 36dB at 772kHz (0 to 6000 feet cable loss) for T1 and from 0 to 43dB at 1024kHz for E1 systems.

In T1 applications, the XRT83VL38 can generate five transmit pulse shapes to meet the short-haul Digital Cross-connect (DSX-1) template requirement as well as four CSU Line Build-Out (LBO) filters of 0dB, -7.5dB, -15dB and -22.5dB as required by FCC rules. It also provides programmable transmit output pulse generators for each channel that can be used for output pulse shaping allowing performance improvement over a wide variety of conditions (The arbitrary pulse generators are available for both T1 and E1, in short-haul configuration). The operation and configuration of the XRT83VL38 can be controlled through a microprocessor **Host** interface (parallel or serial) or **Hardware** control.

MASTER CLOCK GENERATOR

Using a variety of external clock sources, the on-chip frequency synthesizer generates the T1 (1.544MHz) or E1 (2.048MHz) master clocks necessary for the transmit pulse shaping and receive clock recovery circuit.

There are two master clock inputs MCLKE1 and MCLKT1. In systems where both T1 and E1 master clocks are available these clocks can be connected to the respective pins. All channels of a given XRT83VL38 must be operated at the same clock rate, either T1, E1 or J1 modes.

In systems that have only one master clock source available (E1 or T1), that clock should be connected to both MCLKE1 and MCLKT1 inputs for proper operation. T1 or E1 master clocks can be generated from a single 1.544MHz or 2.048MHz external clock under the control of CLKSEL[2:0] inputs according to **Table 1**.

NOTE: EQC[4:0] determine the T1/E1 operating mode. See **Table 5** for details.

FIGURE 4. TWO INPUT CLOCK SOURCE

FIGURE 5. ONE INPUT CLOCK SOURCE

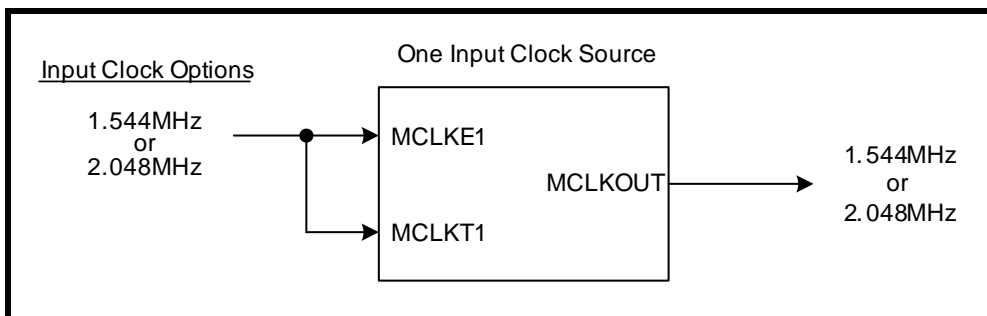

TABLE 1: MASTER CLOCK GENERATOR

MCLKE1 kHz	MCLKT1 kHz	CLKSEL2	CLKSEL1	CLKSEL0	MCLKRATE	MASTER CLOCK kHz
2048	2048	0	0	0	0	2048
2048	2048	0	0	0	1	1544
2048	1544	0	0	0	0	2048
1544	1544	0	0	1	1	1544
1544	1544	0	0	1	0	2048
2048	1544	0	0	1	1	1544

In **Host** mode the programming is achieved through the corresponding interface control bits, the state of the CLKSEL[2:0] control bits and the state of the MCLKRATE interface control bit.

RECEIVER

RECEIVER INPUT

At the receiver input, a cable attenuated AMI signal can be coupled to the receiver through a capacitor or a 1:1 transformer. The input signal is first applied to a selective equalizer for signal conditioning. The maximum equalizer gain is up to 36dB for T1 and 43dB for E1 modes. The equalized signal is subsequently applied to a peak detector which in turn controls the equalizer settings and the data slicer. The slicer threshold for both E1 and T1 is typically set at 50% of the peak amplitude at the equalizer output. After the slicers, the digital representation of the AMI signals are applied to the clock and data recovery circuit. The recovered data subsequently goes through the jitter attenuator and decoder (if selected) for HDB3 or B8ZS decoding before being applied to the RPOS_n/RDATA_n and RNEG_n/LCV_n pins. Clock recovery is accomplished by a digital phase-locked loop (DPLL) which does not require any external components and can tolerate high levels of input jitter that meets or exceeds the ITU-G.823 and TR-TSY000499 standards.

RECEIVE MONITOR MODE

In applications where Monitor mode is desired, the equalizer can be configured in a gain mode which handles input signals attenuated resistively up to 29dB, along with 0 to 6dB cable attenuation for both T1 and E1 applications, refer to **Table 5** for details. This feature is available in both **Hardware** and **Host** modes.

RECEIVER LOSS OF SIGNAL (RLOS)

For compatibility with ITU G.775 requirements, the RLOS monitoring function is implemented using both analog and digital detection schemes. If the analog RLOS condition occurs, a digital detector is activated to count for 32 consecutive zeros in E1 (4096 bits in Extended Los mode, EXLOS = "1") or 175 consecutive zeros in T1 before RLOS is asserted. RLOS is cleared when the input signal rises +3dB (built in hysteresis) above the point at which it was declared and meets 12.5% ones density of 4 ones in a 32 bit window, with no more than 16 consecutive zeros for E1. In T1 mode, RLOS is cleared when the input signal rises +3dB (built in hysteresis) above the point at which it was declared and contains 16 ones in a 128 bit window with no more than 100 consecutive zeros in the data stream. When loss of signal occurs, RLOS register indication and register status will change. If the RLOS register enable is set high (enabled), the alarm will trigger an interrupt causing the interrupt pin (INT) to go low. Once the alarm status register has been read, it will automatically reset upon read (RUR), and the INT pin will return high.

Analog RLOS

Setting the Receiver Inputs to -15dB T1/E1 Short Haul Mode

By setting the receiver inputs to -15dB T1/E1 short haul mode, the equalizer will detect the incoming amplitude and make adjustments by adding gain up to a maximum of +15dB normalizing the T1/E1 input signal.

NOTE: This is the only setting that refers to cable loss (frequency), not flat loss (resistive).

Once the T1/E1 input signal has been normalized to 0dB by adding the maximum gain (+15dB), the receiver will declare RLOS if the signal is attenuated by an additional -9dB. The total cable loss at RLOS declaration is typically -24dB (-15dB + -9dB). A 3dB hysteresis was designed so that transients will not trigger the RLOS to clear. Therefore, the RLOS will typically clear at a total cable attenuation of -21dB. See **Figure 6** for a simplified diagram.

FIGURE 6. SIMPLIFIED DIAGRAM OF -15dB T1/E1 SHORT HAUL MODE AND RLOS CONDITION

Setting the Receiver Inputs to -29dB T1/E1 Gain Mode

By setting the receiver inputs to -29dB T1/E1 gain mode, the equalizer will detect the incoming amplitude and make adjustments by adding gain up to a maximum of +29dB normalizing the T1/E1 input signal.

NOTE: This is the only setting that refers to flat loss (resistive). All other modes refer to cable loss (frequency).

Once the T1/E1 input signal has been normalized to 0dB by adding the maximum gain (+29dB), the receiver will declare RLOS if the signal is attenuated by an additional -9dB. The total cable loss at RLOS declaration is typically -38dB (-29dB + -9dB). A 3dB hysteresis was designed so that transients will not trigger the RLOS to clear. Therefore, the RLOS will typically clear at a total flat loss of -35dB. See **Figure 7** for a simplified diagram.

FIGURE 7. SIMPLIFIED DIAGRAM OF -29dB T1/E1 GAIN MODE AND RLOS CONDITION

Setting the Receiver Inputs to -36dB T1/E1 Long Haul Mode

By setting the receiver inputs to -36dB T1/E1 long haul mode, the equalizer will detect the incoming amplitude and make adjustments by adding gain up to a maximum of +36dB normalizing the T1 input signal. This setting refers to cable loss (frequency), not flat loss (resistive). Once the T1/E1 input signal has been normalized to 0dB by adding the maximum gain (+36dB), the receiver will declare RLOS if the signal is attenuated by an additional -9dB. The total cable loss at RLOS declaration is typically -45dB (-36dB + -9dB). A 3dB hysteresis was designed so that transients will not trigger the RLOS to clear. Therefore, the RLOS will typically clear at a total cable attenuation of -42dB. See **Figure 8** for a simplified diagram.

FIGURE 8. SIMPLIFIED DIAGRAM OF -36dB T1/E1 LONG HAUL MODE AND RLOS CONDITION

E1 Extended RLOS

E1: Setting the Receiver Inputs to Extended RLOS

By setting the receiver inputs to extended RLOS, the equalizer will detect the incoming amplitude and make adjustments by adding gain up to a maximum of +43dB normalizing the E1 input signal. This setting refers to

cable loss (frequency), not flat loss (resistive). Once the E1 input signal has been normalized to 0dB by adding the maximum gain (+43dB), the receiver will declare RLOS if the signal is attenuated by an additional -9dB. The total cable loss at RLOS declaration is typically -52dB (-43dB + -9dB). A 3dB hysteresis was designed so that transients will not trigger the RLOS to clear. Therefore, the RLOS will typically clear at a total cable attenuation of -49dB. See **Figure 9** for a simplified diagram.

FIGURE 9. SIMPLIFIED DIAGRAM OF EXTENDED RLOS MODE (E1 ONLY)

RECEIVE HDB3/B8ZS DECODER

The Decoder function is available in both **Hardware** and **Host** modes on a per channel basis by controlling the TNEG_n/CODES_n pin or the CODES_n interface bit. The decoder function is only active in single-rail Mode. When selected, receive data in this mode will be decoded according to HDB3 rules for E1 and B8ZS for T1 systems. Bipolar violations that do not conform to the coding scheme will be reported as Line Code Violation at the RNEG_n/LCV_n pin of each channel. The length of the LCV pulse is one RCLK cycle for each code violation. In E1mode only, an excessive number of zeros in the receive data stream is also reported as an error at the same output pin. If AMI decoding is selected in single rail mode, every bipolar violation in the receive data stream will be reported as an error at the RNEG_n/LCV_n pin.

RECOVERED CLOCK (RCLK) SAMPLING EDGE

This feature is available in both **Hardware** and **Host** modes on a global basis. In **Host** mode, the sampling edge of RCLK output can be changed through the interface control bit RCLKE. If a "1" is written in the RCLKE interface bit, receive data output at RPOS_n/RDATA_n and RNEG_n/LCV_n are updated on the falling edge of

RCLK for all eight channels. Writing a “0” to the RCLKE register, updates the receive data on the rising edge of RCLK. In **Hardware** mode the same feature is available under the control of the RCLKE pin.

FIGURE 10. RECEIVE CLOCK AND OUTPUT DATA TIMING

JITTER ATTENUATOR

To reduce phase and frequency jitter in the recovered clock, the jitter attenuator can be placed in the receive signal path. The jitter attenuator uses a data FIFO (First In First Out) with a programmable depth that can vary between 2x32 and 2x64. The jitter attenuator can also be placed in the transmit signal path or disabled altogether depending upon system requirements. The jitter attenuator, other than using the master clock as reference, requires no external components. With the jitter attenuator selected, the typical throughput delay from input to output is 16 bits for 32 bit FIFO size or 32 bits for 64 bit FIFO size. When the read and write pointers of the FIFO in the jitter attenuator are within two bits of over-flowing or under-flowing, the bandwidth of the jitter attenuator is widened to track the short term input jitter, thereby avoiding data corruption. When this situation occurs, the jitter attenuator will not attenuate input jitter until the read/write pointer's position is outside the two bits window. Under normal condition, the jitter transfer characteristic meets the narrow bandwidth requirement as specified in ITU- G.736, ITU- I.431 and AT&T Pub 62411 standards.

In T1 mode the Jitter Attenuator Bandwidth is always set to 3Hz. In E1 mode, the bandwidth can be reduced through the JABW control signal. When JABW is set “High” the bandwidth of the jitter attenuator is reduced from 10Hz to 1.5Hz. Under this condition the FIFO length is automatically set to 64 bits and the 32 bits FIFO length will not be available in this mode. Jitter attenuator controls are available on a per channel basis in the **Host** mode and on a global basis in the **Hardware** mode.

GAPPED CLOCK (JA MUST BE ENABLED IN THE TRANSMIT PATH)

The XRT83VL38 LIU is ideal for multiplexer or mapper applications where the network data crosses multiple timing domains. As the higher data rates are de-multiplexed down to T1 or E1 data, stuffing bits are removed which can leave gaps in the incoming data stream. If the jitter attenuator is enabled in the transmit path, the 32-Bit or 64-Bit FIFO is used to smooth the gapped clock into a steady T1 or E1 output. The maximum gap width of the 8-Channel LIU is shown in **Table 2**.

TABLE 2: MAXIMUM GAP WIDTH FOR MULTIPLEXER/MAPPER APPLICATIONS

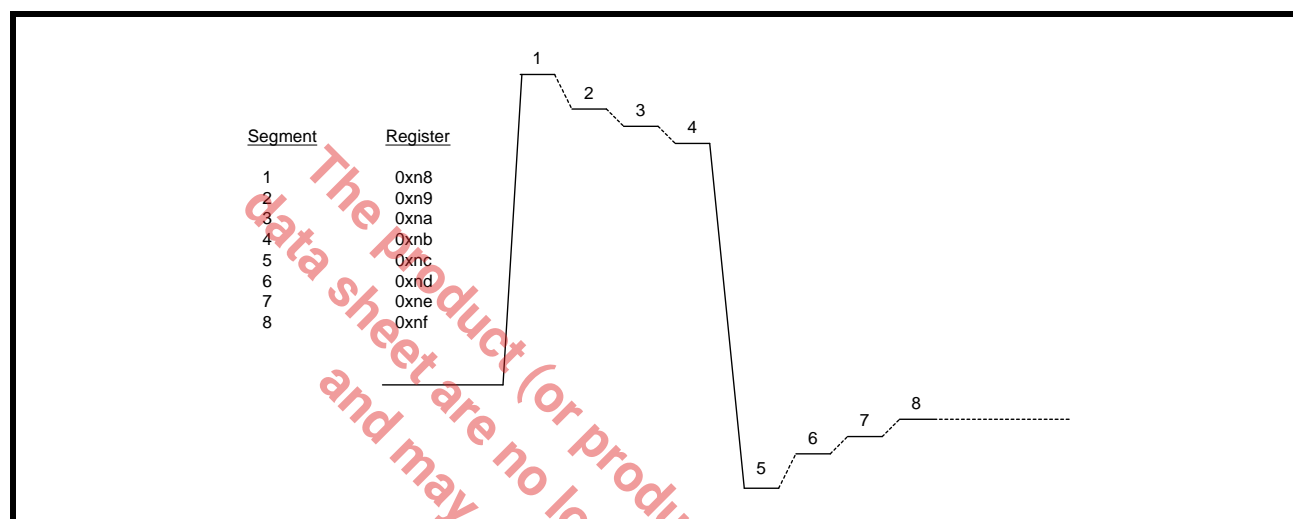

FIFO DEPTH	MAXIMUM GAP WIDTH
32-Bit	20 UI
64-Bit	50 UI

NOTE: If the LIU is used in a loop timing system, the jitter attenuator should be enabled in the receive path.

ARBITRARY PULSE GENERATOR FOR T1 AND E1

The arbitrary pulse generator divides the pulse into eight individual segments. Each segment is set by a 7-Bit binary word by programming the appropriate channel register. This allows the system designer to set the overshoot, amplitude, and undershoot for a unique line build out. The MSB (bit 7) is a sign-bit. If the sign-bit is set to “1”, the segment will move in a positive direction relative to a flat line (zero) condition. If this sign-bit is set to “0”, the segment will move in a negative direction relative to a flat line condition. A pulse with numbered segments is shown in **Figure 11**.

FIGURE 11. ARBITRARY PULSE SEGMENT ASSIGNMENT

NOTE: By default, the arbitrary segments are programmed to 0x00h. The transmitter outputs will result in an all zero pattern to the line. For E1 arbitrary mode, see global register 0xC0h.

TRANSMITTER

DIGITAL DATA FORMAT

Both the transmitter and receiver can be configured to operate in dual or single-rail data formats. This feature is available under both **Hardware** and **Host** control modes, on a global basis. The dual or single-rail data format is determined by the state of the SR/DR pin in **Hardware** mode or SR/DR interface bit in the **Host** mode. In single-rail mode, transmit clock and NRZ data are applied to TCLK_n and TPOS_n/TDATA_n pins respectively. In single-rail and **Hardware** mode the TNEG_n/CODES_n input can be used as the CODES function. With TNEG_n/CODES_n tied “Low”, HDB3 or B8ZS encoding and decoding are enabled for E1 and T1 modes respectively. With TNEG_n/CODES_n tied “High”, the AMI coding scheme is selected. In both dual or single-rail modes of operations, the transmitter converts digital input data to a bipolar format before being transmitted to the line.

TRANSMIT CLOCK (TCLK) SAMPLING EDGE

Serial transmit data at TPOS_n/TDATA_n and TNEG_n/CODES_n are clocked into the XRT83VL38 under the synchronization of TCLK_n. With a “0” written to the TCLKE interface bit, or by pulling the TCLKE pin “Low”, input data is sampled on the falling edge of TCLK_n. The sampling edge is inverted with a “1” written to TCLKE interface bit, or by connecting the TCLKE pin “High”.

FIGURE 12. TRANSMIT CLOCK AND INPUT DATA TIMING

TRANSMIT HDB3/B8ZS ENCODER

The Encoder function is available in both **Hardware** and **Host** modes on a per channel basis by controlling the TNEG_n/CODES_n pin or CODES interface bit. The encoder is only available in single-rail mode. In E1 mode and with HDB3 encoding selected, any sequence with four or more consecutive zeros in the input serial data from TPOS_n/TDATA_n, will be removed and replaced with 000V or B00V, where “B” indicates a pulse conforming with the bipolar rule and “V” representing a pulse violating the rule. An example of HDB3 Encoding is shown in **Table 3**. In a T1 system, an input data sequence with eight or more consecutive zeros will be removed and replaced using the B8ZS encoding rule. An example of Bipolar with 8 Zero Substitution (B8ZS) encoding scheme is shown in **Table 4**. Writing a “1” into the CODES_n interface bit or connecting the TNEG_n/CODES_n pin to a “High” level selects the AMI coding for both E1 or T1 systems.

TABLE 3: EXAMPLES OF HDB3 ENCODING

	NUMBER OF PULSE BEFORE NEXT 4 ZEROS	NEXT 4 BITS

B8ZS		000VB0VB
AMI Output	-	000- +0+ -

DRIVER FAILURE MONITOR (DMO)

The driver monitor circuit is used to detect transmit driver failure by monitoring the activities at TTIP and TRING outputs. Driver failure may be caused by a short circuit in the primary transformer or system problems at the transmit input. If the transmitter of a channel has no output for more than 128 clock cycles, the corresponding DMO pin goes “High” and remains “High” until a valid transmit pulse is detected. In **Host** mode, the failure of the transmit channel is reported in the corresponding interface bit. If the DMOIE bit is also enabled, any transition on the DMO interface bit will generate an interrupt. The driver failure monitor is supported in both **Hardware** and **Host** modes on a per channel basis.

TRANSMIT PULSE SHAPER & LINE BUILD OUT (LBO) CIRCUIT

The transmit pulse shaper circuit uses the high speed clock from the Master timing generator to control the shape and width of the transmitted pulse. The internal high-speed timing generator eliminates the need for a tightly controlled transmit clock (TCLK) duty cycle. With the jitter attenuator not in the transmit path, the transmit output will generate no more than 0.025Unit Interval (UI) peak-to-peak jitter. In **Hardware** mode, the state of the A[4:0]/EQC[4:0] pins determine the transmit pulse shape for all eight channels. In **Host** mode transmit pulse shape can be controlled on a per channel basis using the interface bits EQC[4:0]. The chip supports five fixed transmit pulse settings for T1 Short-haul applications plus a fully programmable waveform generator for arbitrary transmit output pulse shapes (The arbitrary pulse generators are available for both T1 and E1). Transmit Line Build-Outs for T1 long-haul application are supported from 0dB to -22.5dB in three 7.5dB steps. The choice of the transmit pulse shape and LBO under the control of the interface bits are summarized in **Table 5**. For CSU LBO transmit pulse design information, refer to ANSI T1.403-1993 Network-to-Customer Installation specification, Annex-E.

NOTE: EQC[4:0] determine the T1/E1 operating mode of the XRT83VL38. When EQC4 = “1” and EQC3 = “1”, the XRT83VL38 is in the E1 mode, otherwise it is in the T1/J1 mode. For details on how to enable the E1 arbitrary mode, see global register 0xC0h.

TRANSMIT AND RECEIVE TERMINATIONS

The XRT83VL38 is a versatile LIU that can be programmed to use one Bill of Materials (BOM) for worldwide applications for T1, J1 and E1. For specific applications the internal terminations can be disabled to allow the use of existing components and/or designs.

RECEIVER (CHANNELS 0 - 7)

INTERNAL RECEIVE TERMINATION MODE

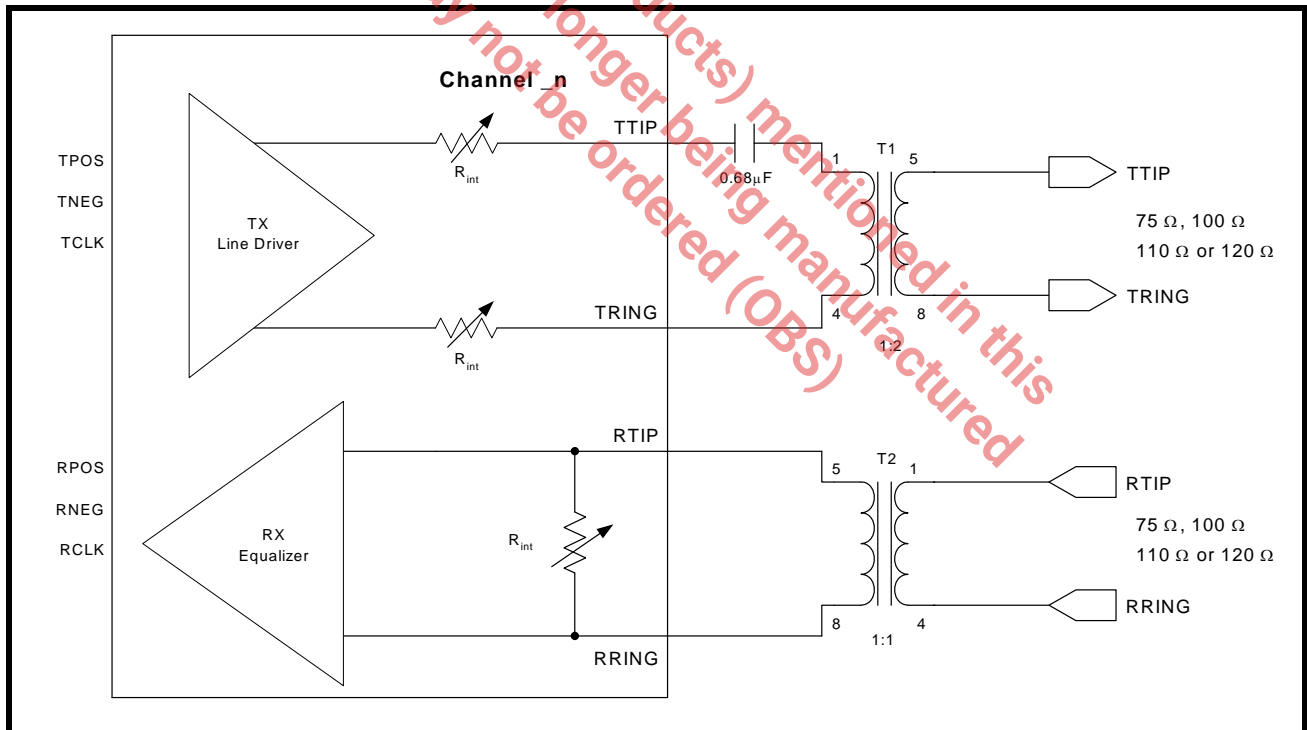

In **Hardware** mode, RXTSEL (Pin 83) can be tied “High” to select internal termination mode for all receive channels or tied “Low” to select external termination mode. Individual channel control can only be done in **Host** mode. By default the XRT83VL38 is set for external termination mode at power up or at **Hardware** reset.

TABLE 6: RECEIVE TERMINATION CONTROL

RXTSEL	RX TERMINATION
0	EXTERNAL
1	INTERNAL

In **Host** mode, bit 7 in the appropriate channel register, (Table 24, “Microprocessor Register #1, Bit Description,” on page 59), is set “High” to select the internal termination mode for that specific receive channel.

FIGURE 13. SIMPLIFIED DIAGRAM FOR THE INTERNAL RECEIVE AND TRANSMIT TERMINATION MODE

If the internal termination mode (RXTSEL = “1”) is selected, the effective impedance for E1, T1 or J1 can be achieved either with an internal resistor or a combination of internal and external resistors as shown in Table 7.

NOTE: In **Hardware** mode, pins RXRES[1:0] control all channels.

TABLE 7: RECEIVE TERMINATIONS

RXTSEL	TERSEL1	TERSEL0	RXRES1	RXRES0	R _{ext}	R _{int}	MODE

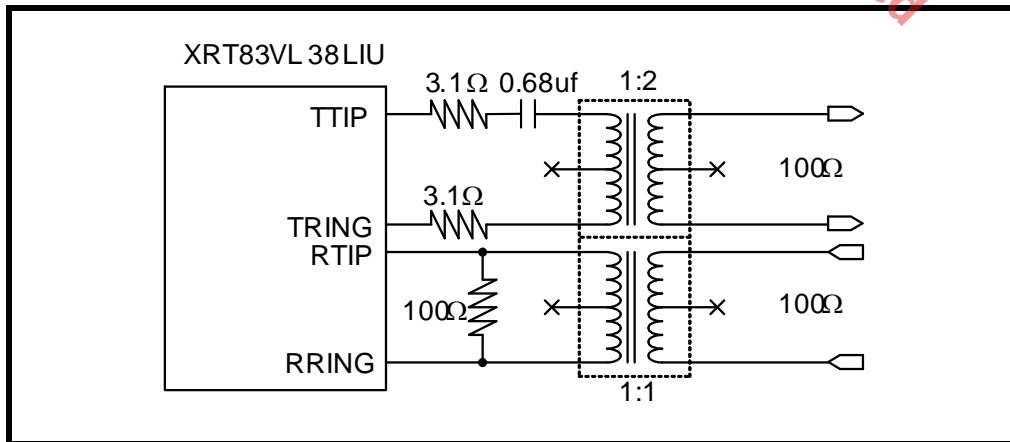

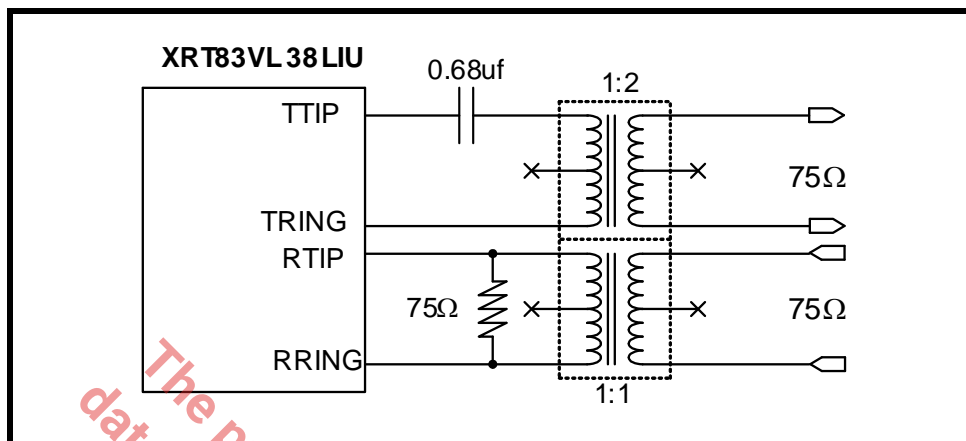

FIGURE 15. SIMPLIFIED DIAGRAM FOR E1 IN EXTERNAL RECEIVE TERMINATION MODE (RXTSEL= 0) AND INTERNAL TRANSMIT TERMINATION MODE (TXTEL= 1)

TRANSMITTER (CHANNELS 0 - 7)
TRANSMIT TERMINATION MODE

In **Hardware** mode, TXTSEL (Pin 84) can be tied “High” to select internal termination mode for all transmit channels or tied “Low” for external termination. Individual channel control can be done only in **Host** mode. In **Host** mode, bit 6 in the appropriate register for a given channel is set “High” to select the internal termination mode for that specific transmit channel, see [Table 24, “Microprocessor Register #1, Bit Description,” on page 59.](#)

In internal mode, no external resistors are used. An external capacitor of 0.68 μ F is used for proper operation of the internal termination circuitry, see [Figure 13.](#)

TABLE 8: TERMINATION SELECT CONTROL

TERSEL1	TERSEL0	TERMINATION
0	0	100 Ω
0	1	110 Ω
1	0	75 Ω
1	1	120 Ω

EXTERNAL TRANSMIT TERMINATION MODE

By default the XRT83VL38 is set for external termination mode at power up or at **Hardware** reset.

When external transmit termination mode is selected, the internal termination circuitry is disabled. The value of the external resistors is chosen for a specific application. [Figure 14](#) is a simplified block diagram for T1 (100 Ω) in the external receive and transmit termination mode. [Figure 15](#) is a simplified block diagram for E1 (75 Ω) in the external receive termination and internal transmit termination mode.

[Table 9](#) summarizes the transmit terminations.

REDUNDANCY APPLICATIONS

Telecommunication system design requires signal integrity and reliability. When a T1/E1 primary line card has a failure, it must be swapped with a backup line card while maintaining connectivity to a backplane without losing data. System designers can achieve this by implementing common redundancy schemes with the XRT83VL38 Line Interface Unit (LIU). The XRT83VL38 offers features that are tailored to redundancy applications while reducing the number of components and providing system designers with solid reference designs. These features allow system designers to implement redundancy applications that ensure reliability. The Internal Impedance mode eliminates the need for external relays when using the 1:1 and 1+1 redundancy schemes.

PROGRAMMING CONSIDERATIONS

In many applications switching the control of the transmitter outputs and the receiver line impedance to **hardware** control will provide faster transmitter ON/OFF switching.

In **Host** Mode, there are two bits in register 130 (82H) that control the transmitter outputs and the Rx line impedance select, TXONCNTL (Bit 7) and TERCNTL (Bit 6).

Setting bit-7 (TXONCNTL) to a “1” transfers the control of the Transmit On/Off function to the TXON_n **Hardware** control pins. (Pins 90 through 93 and pins 169 through 172). The TXON is used to tri-state the transmit outputs when used in a redundancy application.

Setting bit-6 (TERCNTL) to a “1” transfers the control of the Rx line impedance select (RXTSEL) to the RXTSEL **Hardware** control pin (pin 83).

Either mode works well with redundancy applications. The user can determine which mode has the fastest switching time for a unique application.

TYPICAL REDUNDANCY SCHEMES

- n ·1:1 One backup card for every primary card (Facility Protection)
- n ·1+1 One backup card for every primary card (Line Protection)
- n ·N+1 One backup card for N primary cards

1:1 REDUNDANCY

A 1:1 facility protection redundancy scheme has one backup card for every primary card. When using 1:1 redundancy, the backup card has its transmitters tri-stated and its receivers in high impedance. This eliminates the need for external relays and provides one bill of materials for all interface modes of operation. The transmit and receive sections of the LIU device are described separately.

1+1 REDUNDANCY

A 1+1 line protection redundancy scheme has one backup card for every primary card, and the receivers on the backup card are monitoring the receiver inputs. Therefore, the receivers on both cards need to be active. The transmit outputs require no external resistors. The transmit and receive sections of the LIU device are described separately.

TRANSMIT 1:1 & 1+1 REDUNDANCY

For 1:1 and 1+1 redundancy, the transmitters on the primary and backup card should be programmed for Internal Impedance mode. The transmitters on the backup card should be tri-stated. Select the appropriate impedance for the desired mode of operation, T1/E1/J1. A 0.68uF capacitor is used in series with TTIP for blocking DC bias. See **Figure 16** for a simplified block diagram of the transmit section for 1:1 and 1+1 redundancy scheme.

NOTE: For simplification, the over voltage protection circuitry was omitted.

FIGURE 16. SIMPLIFIED BLOCK DIAGRAM OF THE TRANSMIT SECTION FOR 1:1 & 1+1 REDUNDANCY

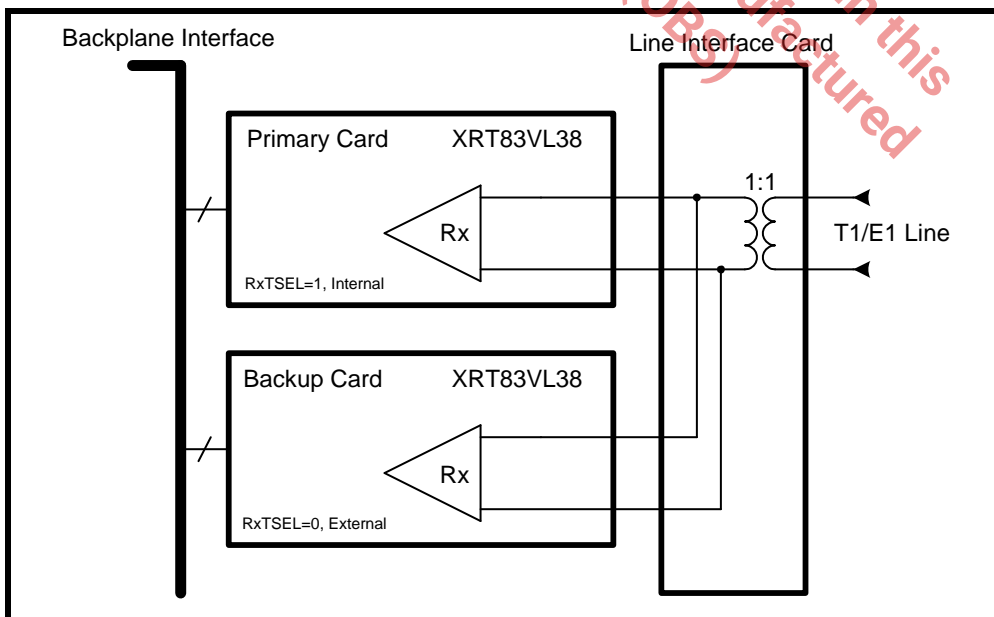

RECEIVE 1:1 & 1+1 REDUNDANCY

For 1:1 and 1+1 redundancy, the receivers on the primary card should be programmed for Internal Impedance mode. The receivers on the backup card should be programmed for External Impedance mode. Since there is no external resistor in the circuit, the receivers on the backup card will be high impedance. This key design feature eliminates the need for relays and provides one bill of materials for all interface modes of operation. Select the impedance for the desired mode of operation, T1/E1/J1. To swap the primary card, set the backup card to Internal Impedance mode, then the primary card to External Impedance mode. See Figure 17 for a simplified block diagram of the receive section for a 1:1 and 1+1 redundancy scheme.

NOTE: For simplification, the over voltage protection circuitry was omitted.

FIGURE 17. SIMPLIFIED BLOCK DIAGRAM - RECEIVE SECTION FOR 1:1 AND 1+1 REDUNDANCY

N+1 REDUNDANCY

N+1 redundancy has one backup card for N primary cards. Due to impedance mismatch and signal contention, external relays are necessary when using this redundancy scheme. The advantage of relays is that they create complete isolation between the primary cards and the backup card. This allows all transmitters and receivers on the primary cards to be configured in internal impedance mode, providing one bill of materials for all interface modes of operation. The transmit and receive sections of the XRT83VL38 are described separately.

TRANSMIT

For N+1 redundancy, the transmitters on all cards should be programmed for internal impedance mode providing one bill of materials for T1/E1/J1. The transmitters on the backup card do not have to be tri-stated. To swap the primary card, close the desired relays, and tri-state the transmitters on the failed primary card. A 0.68µF capacitor is used in series with TTIP for blocking DC bias. See Figure 18 for a simplified block diagram of the transmit section for an N+1 redundancy scheme.

NOTE: For simplification, the over voltage protection circuitry was omitted.

FIGURE 18. SIMPLIFIED BLOCK DIAGRAM - TRANSMIT SECTION FOR N+1 REDUNDANCY

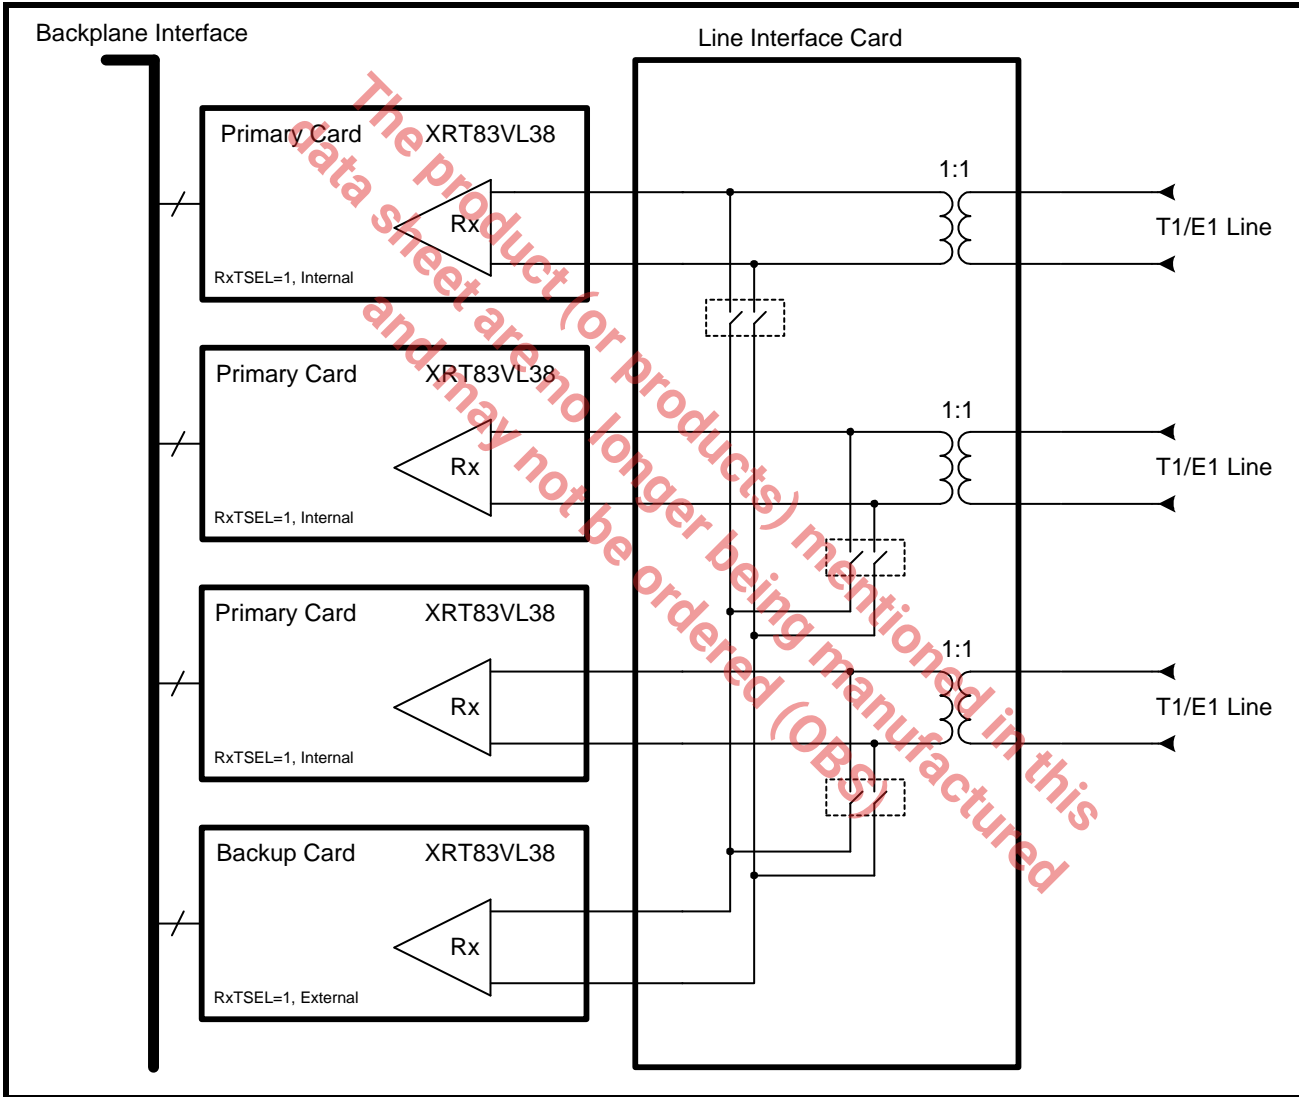

RECEIVE

For N+1 redundancy, the receivers on the primary cards should be programmed for internal impedance mode. The receivers on the backup card should be programmed for external impedance mode. Since there is no external resistor in the circuit, the receivers on the backup card will be high impedance. Select the impedance for the desired mode of operation, T1/E1/J1. To swap the primary card, set the backup card to internal impedance mode, then the primary card to external impedance mode. See **Figure 19**. for a simplified block diagram of the receive section for a N+1 redundancy scheme.

NOTE: For simplification, the over voltage protection circuitry was omitted.

FIGURE 19. SIMPLIFIED BLOCK DIAGRAM - RECEIVE SECTION FOR N+1 REDUNDANCY

PATTERN TRANSMIT AND DETECT FUNCTION

Several test and diagnostic patterns can be generated and detected by the chip. In **Hardware** mode each channel can be independently programmed to transmit an All Ones pattern by applying a “High” level to the corresponding TAOS_n pin. In **Host** mode, the three interface bits TXTEST[2:0] control the pattern generation and detection independently for each channel according to **Table 10**.

TABLE 10: PATTERN TRANSMISSION CONTROL

TXTEST2	TXTEST1	TXTEST0	TEST PATTERN
0	x	x	None
1	0	0	TDQRSS
1	0	1	TAOS
1	1	0	TLUC
	1	1	TLDC

TRANSMIT ALL ONES (TAOS)

This feature is available in both **Hardware** and **Host** modes. With the TAOS_n pin connected to a “High” level or when interface bits TXTEST2=“1”, TXTEST1=“0” and TXTEST0=“1” the transmitter ignores input from TPOS_n/TDATA_n and TNEG_n/CODES_n pins and sends a continuous AMI encoded all “Ones” signal to the line, using TCLK_n clock as the reference. In addition, when the **Hardware** pin and interface bit ATAOS is activated, the chip will automatically transmit the All “Ones” data from any channel that detects an RLOS condition. This feature is not available on a per channel basis. TCLK_n must NOT be tied “Low”.

NETWORK LOOP CODE DETECTION AND TRANSMISSION

This feature is available in **Host** mode only. When the interface bits TXTEST2=“1”, TXTEST1=“1” and TXTEST0=“0” the chip is enabled to transmit the “00001” Network Loop-Up Code from the selected channel requesting a Loop-Back condition from the remote terminal. Simultaneously setting the interface bits NLCDE1=“0” and NLCDE0=“1” enables the Network Loop-Up code detection in the receiver. If the “00001” Network Loop-Up code is detected in the receive data for longer than 5 seconds, the NLCD bit in the interface register is set indicating that the remote terminal has activated remote Loop-Back and the chip is receiving its own transmitted data. When the interface bits TXTEST2=“1”, TXTEST1=“1” and TXTEST0=“1” the chip is enabled to transmit the Network Loop-Down Code (TLDC) “001” from the selected channel requesting the remote terminal the removal of the Loop-Back condition.

In the **Host** mode each channel is capable of monitoring the contents of the receive data for the presence of Loop-Up or Loop-Down code from the remote terminal. In the **Host** mode the two interface bits NLCDE[1:0] control the Loop-Code detection independently for each channel according to **Table 11**.

TABLE 11: LOOP-CODE DETECTION CONTROL

NLCDE1	NLCDE0	CONDITION
0	0	Disable Loop-Code Detection
0	1	Detect Loop-Up Code in Receive Data
1	0	Detect Loop-Down Code in Receive Data
1	1	Automatic Loop-Code detection and Remote Loop-Back Activation

Setting the interface bits to NLCDE1=“0” and NLCDE0=“1” activates the detection of the Loop-Up code in the receive data. If the “00001” Network Loop-Up code is detected in the receive data for longer than 5 seconds, the NLCD interface bit is set to “1” and stays in this state for as long as the receiver continues to receive the

Network Loop-Up Code. In this mode if the NLCD interrupt is enabled, the chip will initiate an interrupt on every transition of NLCD. The host has the option to ignore the request from the remote terminal, or to respond to the request and manually activate Remote Loop-Back. The host can subsequently activate the detection of the Loop-Down Code by setting NLCDE1="1" and NLCDE0="0". In this case, receiving the "001" Loop-Down Code for longer than 5 seconds will set the NLCD bit to "1" and if the NLCD interrupt is enabled, the chip will initiate an interrupt on every transition of NLCD. The host can respond to the request from the remote terminal and remove Loop-Back condition. In the manual Network Loop-Up (NLCDE1="0" and NLCDE0="1") and Loop-Down (NLCDE1="1" and NLCDE0="0") Code detection modes, the NLCD interface bit will be set to "1" upon receiving the corresponding code in excess of 5 seconds in the receive data. The chip will initiate an interrupt any time the status of the NLCD bit changes and the Network Loop-code interrupt is enabled.

In the **Host** mode, setting the interface bits NLCDE1="1" and NLCDE0="1" enables the automatic Loop-Code detection and Remote Loop-Back activation mode if, TXTEST[2:0] is NOT equal to "110". As this mode is initiated, the state of the NLCD interface bit is reset to "0" and the chip is programmed to monitor the receive input data for the Loop-Up Code. If the "00001" Network Loop-Up Code is detected in the receive data for longer than 5 seconds in addition to the NLCD bit in the interface register being set, Remote Loop-Back is automatically activated. The chip stays in remote Loop-Back even if it stops receiving the "00001" pattern. After the chip detects the Loop-Up code, sets the NLCD bit and enters Remote Loop-Back, it automatically starts monitoring the receive data for the Loop-Down code. In this mode however, the NLCD bit stays set even if the receiver stops receiving the Loop-Up code, which is an indication to the host that the Remote Loop-Back is still in effect. Remote Loop-Back is removed if the chip detects the "001" Loop-Down code for longer than 5 seconds. Detecting the "001" code also results in resetting the NLCD interface bit and initiating an interrupt. The Remote Loop-Back can also be removed by taking the chip out of the Automatic detection mode by programming it to operate in a different state. The chip will not respond to remote Loop-Back request if Local Analog Loop-Back is activated locally. When programmed in Automatic detection mode the NLCD interface bit stays "High" for the whole time the Remote Loop-Back is activated and initiates an interrupt any time the status of the NLCD bit changes provided the Network Loop-code interrupt is enabled.

TRANSMIT AND DETECT QUASI-RANDOM SIGNAL SOURCE (TDQRSS)

Each channel of XRT83VL38 includes a QRSS pattern generation and detection block for diagnostic purposes that can be activated only in the **Host** mode by setting the interface bits TXTEST2="1", TXTEST1="0" and TXTEST0="0". For T1 systems, the QRSS pattern is a $2^{20}-1$ pseudo-random bit sequence (PRBS) with no more than 14 consecutive zeros. For E1 systems, the QRSS pattern is $2^{15}-1$ PRBS with an inverted output. With QRSS and Analog Local Loop-Back enabled simultaneously, and by monitoring the status of the QRPD interface bit, all main functional blocks within the transceiver can be verified.

When the receiver achieves QRSS synchronization with fewer than 4 errors in a 128 bits window, QRPD changes from "Low" to "High". After pattern synchronization, any bit error will cause QRPD to go "Low" for one clock cycle. If the QRPDIE bit is enabled, any transition on the QRPD bit will generate an interrupt.

With TDQRSS activated, a bit error can be inserted in the transmitted QRSS pattern by transitioning the INSBER interface bit from "0" to "1". Bipolar violation can also be inserted either in the QRSS pattern, or input data when operating in the single-rail mode by transitioning the INSBPV interface bit from "0" to "1". The state of INSBER and INSBPV bits are sampled on the rising edge of the TCLK_n. To insure the insertion of the bit error or bipolar violation, a "0" should be written in these bit locations before writing a "1".

LOOP-BACK MODES

The XRT83VL38 supports several Loop-Back modes under both **Hardware** and **Host** control. In **Hardware** mode the two LOOP[1:0] pins control the Loop-Back functions for each channel independently according to **Table 12**.

TABLE 12: LOOP-BACK CONTROL IN HARDWARE MODE

LOOP1	LOOP0	LOOP-BACK MODE
0	0	None
0	1	Analog
1	0	Remote
1	1	Digital

In **Host** mode the Loop-Back functions are controlled by the three LOOP[2:0] interface bits. Each channel can be programmed independently according to **Table 13**.

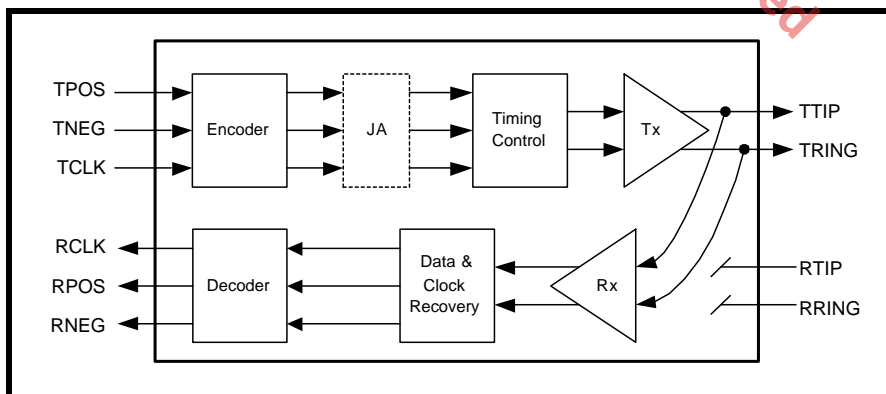

TABLE 13: LOOP-BACK CONTROL IN HOST MODE

LOOP2	LOOP1	LOOP0	LOOP-BACK MODE
0	X	X	None
1	0	0	Dual
1	0	1	Analog
1	1	0	Remote
1	1	1	Digital

LOCAL ANALOG LOOP-BACK (ALOOP)

With Local Analog Loop-Back activated, the transmit data at TTIP and TRING are looped-back to the analog input of the receiver. External inputs at RTIP/RRING in this mode are ignored while valid transmit data continues to be sent to the line. Local Analog Loop-Back exercises most of the functional blocks of the XRT83VL38 including the jitter attenuator which can be selected in either the transmit or receive paths. Local Analog Loop-Back is shown in **Figure 20**.

FIGURE 20. LOCAL ANALOG LOOP-BACK SIGNAL FLOW

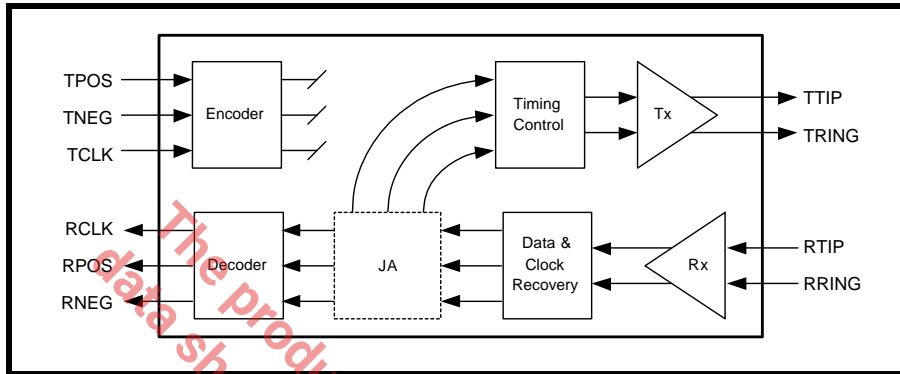

In this mode, the jitter attenuator (if selected) can be placed in the transmit or receive path.

REMOTE LOOP-BACK (RLOOP)

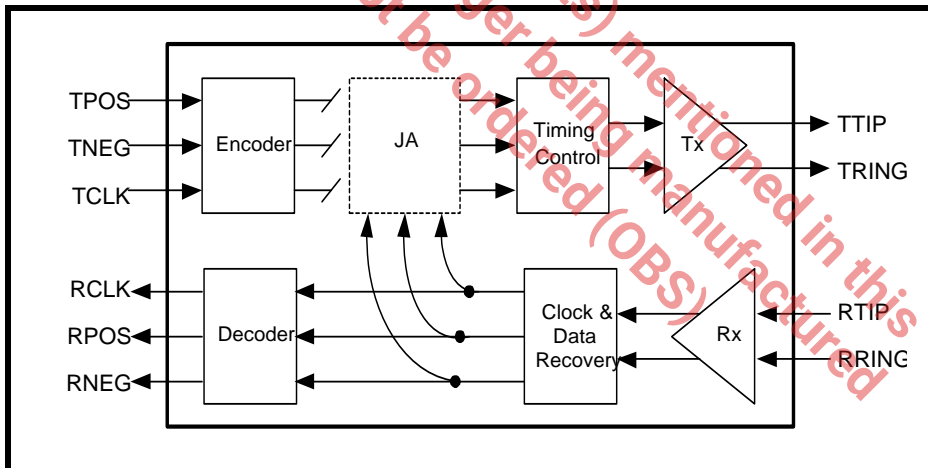

With Remote Loop-Back activated, receive data after the jitter attenuator (if selected in the receive path) is looped back to the transmit path using RCLK as transmit timing. In this mode transmit clock and data are ignored, while RCLK and receive data will continue to be available at their respective output pins. Remote Loop-Back with jitter attenuator selected in the receive path is shown in **Figure 21**.

FIGURE 21. REMOTE LOOP-BACK MODE WITH JITTER ATTENUATOR SELECTED IN RECEIVE PATH

In the Remote Loop-Back mode if the jitter attenuator is selected in the transmit path, the receive data from the Clock and Data Recovery block is looped back to the transmit path and is applied to the jitter attenuator using RCLK as transmit timing. In this mode the transmit clock and data are also ignored, while RCLK and received data will continue to be available at their respective output pins. Remote Loop-Back with the jitter attenuator selected in the transmit path is shown in **Figure 22**.

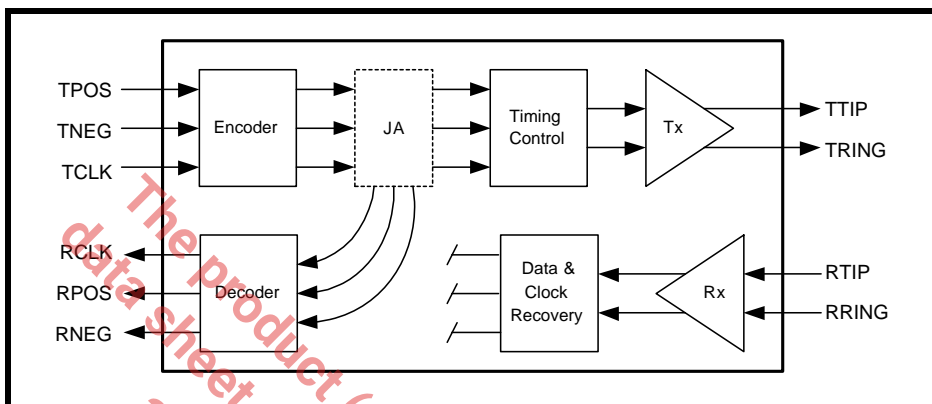

FIGURE 22. REMOTE LOOP-BACK MODE WITH JITTER ATTENUATOR SELECTED IN TRANSMIT PATH

DIGITAL LOOP-BACK (DLOOP)

Digital Loop-Back or Local Loop-Back allows the transmit clock and data to be looped back to the corresponding receiver output pins through the encoder/decoder and jitter attenuator. In this mode, receive data and clock are ignored, but the transmit data will be sent to the line uninterrupted. This loop back feature allows users to configure the line interface as a pure jitter attenuator. The Digital Loop-Back signal flow is shown in **Figure 23**.

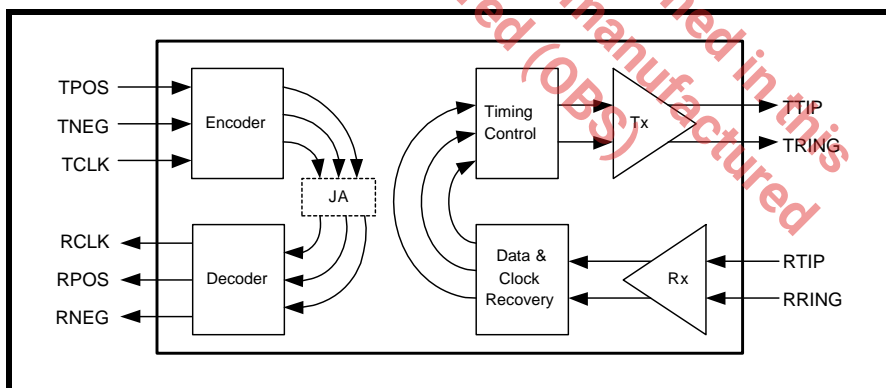

FIGURE 23. DIGITAL LOOP-BACK MODE WITH JITTER ATTENUATOR SELECTED IN TRANSMIT PATH

DUAL LOOP-BACK

Figure 24 depicts the data flow in dual-loopback. In this mode, selecting the jitter attenuator in the transmit path will have the same result as placing the jitter attenuator in the receive path. In dual Loop-Back mode the recovered clock and data from the line are looped back through the transmitter to the TTIP and TRING without passing through the jitter attenuator. The transmit clock and data are looped back through the jitter attenuator to the RCLK and RPOS/RDATA and RNEG pins. For proper operation of Dual Loop-Back mode, TCLK must be present.

FIGURE 24. SIGNAL FLOW IN DUAL LOOP-BACK MODE

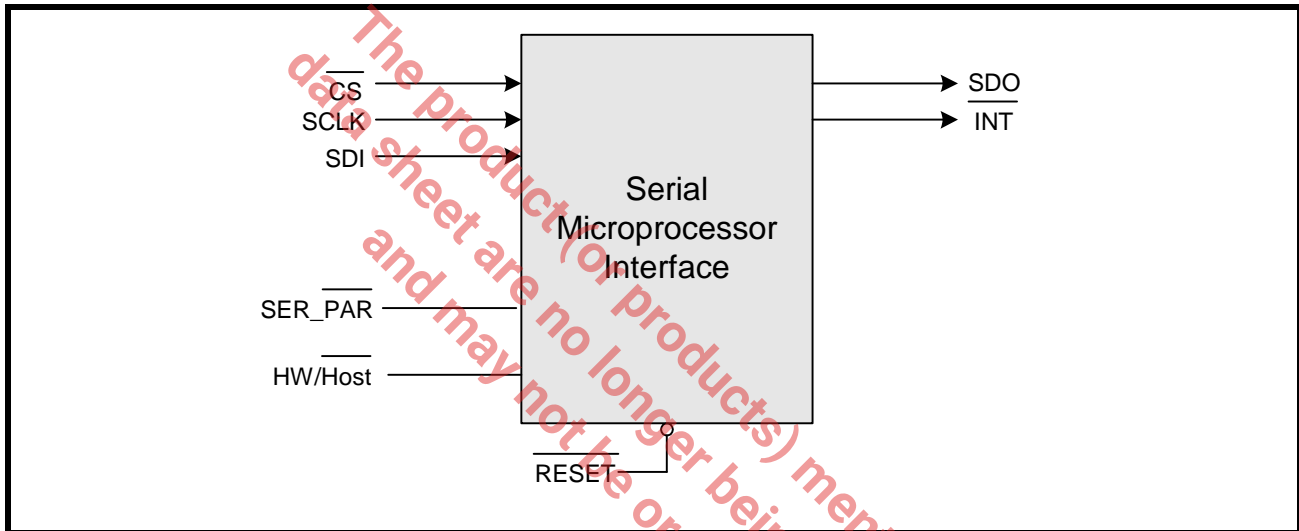

MICROPROCESSOR INTERFACE

The microprocessor interface can be accessed through a standard serial interface or a standard parallel microprocessor interface. The SER_PAR pin is used to select between the two. By default, the chip is configured in the Parallel Microprocessor interface. For Serial communication, this pin must be pulled “High”.

SERIAL MICROPROCESSOR INTERFACE BLOCK

The serial microprocessor uses a standard 3-pin serial port with \overline{CS} , SCLK, and SDI for programming the LIU. Optional pins such as SDO, \overline{INT} , and \overline{RESET} allow the ability to read back contents of the registers, monitor the LIU via an interrupt pin, and reset the LIU to its default configuration by pulling reset “Low” for more than 10 μ S. A simplified block diagram of the Serial Microprocessor is shown in **Figure 25**.

FIGURE 25. SIMPLIFIED BLOCK DIAGRAM OF THE SERIAL MICROPROCESSOR INTERFACE

SERIAL TIMING INFORMATION

The serial port requires 24 bits of data applied to the SDI (Serial Data Input) pin. The Serial Microprocessor samples SDI on the rising edge of SCLK (Serial Clock Input). The data is not latched into the device until all 24 bits of serial data have been sampled. A timing diagram of the Serial Microprocessor is shown in **Figure 26**.

FIGURE 26. TIMING DIAGRAM FOR THE SERIAL MICROPROCESSOR INTERFACE

NOTE: For applications without a free running SCLK, a minimum of 1 SCLK pulse must be applied when \overline{CS} is “High”, before pulling \overline{CS} “Low”.

24-BIT SERIAL DATA INPUT DESCRIPTION

The serial data input is sampled on the rising edge of SCLK. In readback mode, the serial data output is updated on the falling edge of SCLK. The serial data must be applied to the LIU LSB first. The 24 bits of serial data are described below.

ADDR[7:0] (SCLK1 - SCLK8)

The first 8 SCLK cycles are used to provide the address to which a Read or Write operation will occur. ADDR[0] (LSB) must be sent to the LIU first followed by ADDR[1] and so forth until all 8 address bits have been sampled by SCLK.

R/W (SCLK9)

The next serial bit applied to the LIU informs the microprocessor that a Read or Write operation is desired. If the R/W bit is set to "0", the microprocessor is configured for a Write operation. If the R/W bit is set to "1", the microprocessor is configured for a Read operation.

DUMMY BITS (SCLK10 - SCLK16)

The next 7 SCLK cycles are used as dummy bits. Seven bits were chosen so that the serial interface can easily be divided into three 8-bit words to be compliant with standard serial interface devices. The state of these bits are ignored and can hold either "0" or "1" during both Read and Write operations.

DATA[7:0] (SCLK17 - SCLK24)

The next 8 SCLK cycles are used to provide the data to be written into the internal register chosen by the address bits. DATA[0] (LSB) must be sent to the LIU first followed by DATA[1] and so forth until all 8 data bits have been sampled by SCLK. Once 24 SCLK cycles have been completed, the LIU holds the data until CS is pulled "High" whereby, the serial microprocessor latches the data into the selected internal register.

8-BIT SERIAL DATA OUTPUT DESCRIPTION

The serial data output is updated on the falling edge of SCLK17 - SCLK24 if R/W is set to "1". DATA[0] (LSB) is provided on SCLK17 to the SDO pin first followed by DATA[1] and so forth until all 8 data bits have been updated. The SDO pin allows the user to read the contents stored in individual registers by providing the desired address on the SDI pin during the Read cycle.

FIGURE 27. TIMING DIAGRAM FOR THE MICROPROCESSOR SERIAL INTERFACE

PARALLEL MICROPROCESSOR INTERFACE BLOCK

The Parallel Microprocessor Interface section supports communication between the local microprocessor (μP) and the LIU. The XRT83VL38 supports an Intel asynchronous interface and Motorola 68K asynchronous interface. The microprocessor interface is selected by the state of the $\mu\text{PTS}[2:1]$ input pins. Selecting the microprocessor interface is shown in [Table 15](#).

TABLE 15: SELECTING THE MICROPROCESSOR INTERFACE MODE

$\mu\text{PTS}[2:1]$	MICROPROCESSOR MODE
0h (00)	Intel 68HC11, 8051, 80C188 (Asynchronous)
1h (01)	Motorola 68K (Asynchronous)

The XRT83VL38 uses multipurpose pins to configure the device appropriately. The local μP configures the LIU by writing data into specific addressable, on-chip Read/Write registers. The microprocessor interface provides the signals which are required for a general purpose microprocessor to read or write data into these registers. The microprocessor interface also supports polled and interrupt driven environments. A simplified block diagram of the microprocessor is shown in [Figure 28](#).

FIGURE 28. SIMPLIFIED BLOCK DIAGRAM OF THE MICROPROCESSOR INTERFACE BLOCK

THE MICROPROCESSOR INTERFACE BLOCK SIGNALS

The LIU may be configured into different operating modes and have its performance monitored by software through a standard microprocessor using data, address and control signals. These interface signals are described below in [Table 16](#), [Table 17](#), and [Table 18](#). The microprocessor interface can be configured to operate in Intel mode or Motorola mode. When the microprocessor interface is operating in Intel mode, some of the control signals function in a manner required by the Intel 80xx family of microprocessors. Likewise, when the microprocessor interface is operating in Motorola mode, then these control signals function in a manner as required by the Motorola microprocessors. (For using a Motorola 68K asynchronous processor, see [Figure 30](#) and [Table 20](#)) [Table 16](#) lists and describes those microprocessor interface signals whose role is constant across the two modes. [Table 17](#) describes the role of some of these signals when the microprocessor interface is operating in the Intel mode. Likewise, [Table 18](#) describes the role of these signals when the microprocessor interface is operating in the Motorola Power PC mode.

TABLE 16: XRT83VL38 MICROPROCESSOR INTERFACE SIGNALS THAT EXHIBIT CONSTANT ROLES IN BOTH INTEL AND MOTOROLA MODES

PIN NAME	TYPE	DESCRIPTION
μPTS[2:1]	I	Microprocessor Interface Mode Select Input pins These two pins are used to specify the microprocessor interface mode. The relationship between the state of these two input pins, and the corresponding microprocessor mode is presented in Table 15 .
DATA[7:0]	I/O	Bi-Directional Data Bus for register "Read" or "Write" Operations.
ADDR[7:0]	I	Eight-Bit Address Bus Inputs The XRT83VL38 LIU microprocessor interface uses a direct address bus. This address bus is provided to permit the user to select an on-chip register for Read/Write access.
$\overline{\text{CS}}$	I	Chip Select Input This active low signal selects the microprocessor interface of the XRT83VL38 LIU and enables Read/Write operations with the on-chip register locations.

TABLE 17: INTEL MODE: MICROPROCESSOR INTERFACE SIGNALS

XRT83VL38 PIN NAME	INTEL EQUIVALENT PIN	TYPE	DESCRIPTION
ALE	ALE	I	Address-Latch Enable: This active high signal is used to latch the contents on the address bus ADDR[7:0]. The contents of the address bus are latched into the ADDR[7:0] inputs on the falling edge of ALE.
$\overline{\text{RD}}_{\text{DS}}$	$\overline{\text{RD}}$	I	Read Signal: This active low input functions as the read signal from the local μP . When this pin is pulled "Low" (if $\overline{\text{CS}}$ is "Low") the LIU is informed that a read operation has been requested and begins the process of the read cycle.
$\overline{\text{WR}}_{\text{R/W}}$	$\overline{\text{WR}}$	I	Write Signal: This active low input functions as the write signal from the local μP . When this pin is pulled "Low" (if $\overline{\text{CS}}$ is "Low") the LIU is informed that a write operation has been requested and begins the process of the write cycle.
$\overline{\text{RDY}}$	$\overline{\text{RDY}}$	O	Ready Output: This active low signal is provided by the LIU device. It indicates that the current read or write cycle is complete, and the LIU is waiting for the next command.

TABLE 18: MOTOROLA MODE: MICROPROCESSOR INTERFACE SIGNALS

XRT83VL38 PIN NAME	MOTOROLA EQUIVALENT PIN	TYPE	DESCRIPTION
ALE	AS	I	Address Strobe: This active high signal is used to latch the contents on the address bus ADDR[7:0]. The contents of the address bus are latched into the ADDR[7:0] inputs on the falling edge of AS.
$\overline{\text{WR}}_{\text{R/W}}$	R/W	I	Read/Write: This input pin from the local μP is used to inform the LIU whether a Read or Write operation has been requested. When this pin is pulled "High", DS will initiate a read operation. When this pin is pulled "Low", DS will initiate a write operation.
$\overline{\text{RD}}_{\text{DS}}$	DS	I	Data Strobe: This active low input functions as the read or write signal from the local μP dependent on the state of R/W. When DS is pulled "Low" (if CS is "Low") the LIU begins the read or write operation.
$\overline{\text{RDY}}$	$\overline{\text{DTACK}}$	O	Data Transfer Acknowledge: This active low signal is provided by the LIU device. It indicates that the current read or write cycle is complete, and the LIU is waiting for the next command.

INTEL MODE PROGRAMMED I/O ACCESS (ASYNCHRONOUS)

If the LIU is interfaced to an Intel type μP , then it should be configured to operate in the Intel mode. Intel type Read and Write operations are described below.

Intel Mode Read Cycle

Whenever an Intel-type μP wishes to read the contents of a register, it should do the following.

1. Place the address of the target register on the address bus input pins ADDR[7:0].
2. While the μP is placing this address value on the address bus, the address decoding circuitry should assert the CS pin of the LIU, by toggling it "Low". This action enables further communication between the μP and the LIU microprocessor interface block.
3. Toggle the ALE input pin "High". This step enables the address bus input drivers, within the microprocessor interface block of the LIU.
4. The μP should then toggle the ALE pin "Low". This step causes the LIU to latch the contents of the address bus into its internal circuitry. At this point, the address of the register has now been selected.

5. Next, the μP should indicate that this current bus cycle is a Read operation by toggling the $\overline{\text{RD}}$ input pin "Low". This action also enables the bi-directional data bus output drivers of the LIU.
6. After the μP toggles the Read signal "Low", the LIU will toggle the $\overline{\text{RDY}}$ output pin "Low". The LIU does this in order to inform the μP that the data is available to be read by the μP , and that it is ready for the next command.
7. After the μP detects the $\overline{\text{RDY}}$ signal and has read the data, it can terminate the Read Cycle by toggling the $\overline{\text{RD}}$ input pin "High".

NOTE: $\overline{\text{ALE}}$ can be tied "High" if this signal is not available.

The Intel Mode Write Cycle

Whenever an Intel type μP wishes to write a byte or word of data into a register within the LIU, it should do the following.

1. Place the address of the target register on the address bus input pins ADDR[7:0].
2. While the μP is placing this address value on the address bus, the address decoding circuitry should assert the $\overline{\text{CS}}$ pin of the LIU, by toggling it "Low". This action enables further communication between the μP and the LIU microprocessor interface block.
3. Toggle the ALE input pin "High". This step enables the address bus input drivers, within the microprocessor interface block of the LIU.
4. The μP should then toggle the ALE pin "Low". This step causes the LIU to latch the contents of the address bus into its internal circuitry. At this point, the address of the register has now been selected.
5. The μP should then place the byte or word that it intends to write into the target register, on the bi-directional data bus DATA[7:0].
6. Next, the μP should indicate that this current bus cycle is a Write operation by toggling the $\overline{\text{WR}}$ input pin "Low". This action also enables the bi-directional data bus input drivers of the LIU.
7. After the μP toggles the Write signal "Low", the LIU will toggle the $\overline{\text{RDY}}$ output pin "Low". The LIU does this in order to inform the μP that the data has been written into the internal register location, and that it is ready for the next command.

NOTE: $\overline{\text{ALE}}$ can be tied "High" if this signal is not available.

The Intel Read and Write timing diagram is shown in [Figure 29](#). The timing specifications are shown in [Table 19](#).

MOTOROLA MODE PROGRAMMED I/O ACCESS (ASYNCHRONOUS)

If the LIU is interfaced to a Motorola type μP , it should be configured to operate in the Motorola mode. Motorola type programmed I/O Read and Write operations are described below.

Motorola Mode Read Cycle

Whenever a Motorola type μP wishes to read the contents of a register, it should do the following.

1. Place the address of the target register on the address bus input pins ADDR[7:0].
2. While the μP is placing this address value on the address bus, the address decoding circuitry should assert the \overline{CS} pin of the LIU, by toggling it "Low". This action enables further communication between the μP and the LIU microprocessor interface block.
3. The μP should then toggle the AS pin "Low". This step causes the LIU to latch the contents of the address bus into its internal circuitry. At this point, the address of the register has now been selected.
4. Next, the μP should indicate that this current bus cycle is a Read operation by pulling the $\overline{R/\overline{W}}$ input pin "High".
5. Toggle the DS input pin "Low". This action enables the bi-directional data bus output drivers of the LIU.
6. After the μP toggles the DS signal "Low", the LIU will toggle the \overline{DTACK} output pin "Low". The LIU does this in order to inform the μP that the data is available to be read by the μP , and that it is ready for the next command.
7. After the μP detects the \overline{DTACK} signal and has read the data, it can terminate the Read Cycle by toggling the DS input pin "High".

Motorola Mode Write Cycle

Whenever a motorola type μP wishes to write a byte or word of data into a register within the LIU, it should do the following.

1. Place the address of the target register on the address bus input pins ADDR[7:0].
2. While the μP is placing this address value on the address bus, the address decoding circuitry should assert the \overline{CS} pin of the LIU, by toggling it "Low". This action enables further communication between the μP and the LIU microprocessor interface block.
3. The μP should then toggle the AS pin "Low". This step causes the LIU to latch the contents of the address bus into its internal circuitry. At this point, the address of the register has now been selected.
4. Next, the μP should indicate that this current bus cycle is a Write operation by pulling the $\overline{R/\overline{W}}$ input pin "Low".
5. Toggle the DS input pin "Low". This action enables the bi-directional data bus output drivers of the LIU.
6. After the μP toggles the DS signal "Low", the LIU will toggle the \overline{DTACK} output pin "Low". The LIU does this in order to inform the μP that the data has been written into the internal register location, and that it is ready for the next command.

7. After the μP detects the \overline{DTACK} signal and has read the data, it can terminate the Read Cycle by toggling the DS input pin "High".

The Motorola Read and Write timing diagram is shown in **Figure 30**. The timing specifications are shown in **Table 20**.

MICROPROCESSOR REGISTER TABLES

The microprocessor interface consists of 256 addressable locations. Each channel uses 16 dedicated 8 byte registers for independent programming and control. There are four additional registers for global control of all channels and two registers for device identification and revision numbers. The remaining registers are for factory test and future expansion. The control register map and the function of the individual bits are summarized in **Table 21** and **Table 22** respectively.

TABLE 21: MICROPROCESSOR REGISTER ADDRESS

REGISTER NUMBER	REGISTER ADDRESS		FUNCTION

TABLE 28: MICROPROCESSOR REGISTER #5, BIT DESCRIPTION

D3	NLCD_n	<p>Network Loop-Code Detection: This bit operates differently in the Manual or the Automatic Network Loop-Code detection modes.</p> <p>In the Manual Loop-Code detection mode, (NLCDE1 = “0” and NLCDE0 = “1” or NLCDE1 = “1” and NLCDE0 = “0”) this bit gets set to “1” as soon as the Loop-Up (“00001”) or Loop-Down (“001”) code is detected in the receive data for longer than 5 seconds. The NLCD bit stays in the “1” state for as long as the chip detects the presence of the Loop-code in the receive data and it is reset to “0” as soon as it stops receiving it. In this mode, if the NLCD interrupt is enabled, the chip will initiate an interrupt on every transition of the NLCD.</p> <p>When the Automatic Loop-code detection mode, (NLCDE1 = “1” and NLCDE0 = “1”) is initiated, the state of the NLCD interface bit is reset to “0” and the chip is programmed to monitor the receive input data for the Loop-Up code. This bit is set to a “1” to indicate that the Network Loop Code is detected for more than 5 seconds. Simultaneously the Remote Loop-Back condition is automatically activated and the chip is programmed to monitor the receive data for the Network Loop Down code. The NLCD bit stays in the “1” state for as long as the Remote Loop-Back condition is in effect even if the chip stops receiving the Loop-Up code. Remote Loop-Back is removed if the chip detects the “001” pattern for longer than 5 seconds in the receive data. Detecting the “001” pattern also results in resetting the NLCD interface bit and initiating an interrupt provided the NLCD interrupt enable bit is active.</p> <p>When programmed in Automatic detection mode, the NLCD interface bit stays “high” for the entire time the Remote Loop-Back is active and initiate an interrupt anytime the status of the NLCD bit changes. In this mode, the Host can monitor the state of the NLCD bit to determine if the Remote Loop-Back is activated.</p>	RO	0
D2	AISD_n	<p>Alarm Indication Signal Detect: This bit is set to a “1” to indicate All Ones Signal is detected by the receiver. The value of this bit is based on the current status of Alarm Indication Signal detector of channel n. If the AISDIE bit is enabled, any transition on this bit will generate an Interrupt.</p>	RO	0
D1	RLOS_n	<p>Receive Loss of Signal: This bit is set to a “1” to indicate that the receive input signal is lost. The value of this bit is based on the current status of the receive input signal of channel n. If the RLOSIE bit is enabled, any transition on this bit will generate an Interrupt.</p>	RO	0
D0	QRPD_n	<p>Quasi-random Pattern Detection: This bit is set to a “1” to indicate the receiver is currently in synchronization with QRSS pattern. The value of this bit is based on the current status of Quasi-random pattern detector of channel n. If the QRPDIE bit is enabled, any transition on this bit will generate an Interrupt.</p>	RO	0

TABLE 39: MICROPROCESSOR REGISTER #128, BIT DESCRIPTION

REGISTER ADDRESS 10000000	NAME	FUNCTION	REGISTER TYPE	RESET VALUE
BIT #				
D7	SR/DR	Single-rail/Dual-rail Select: Writing a "1" to this bit configures all 8 channels in the XRT83VL38 to operate in the Single-rail mode. Writing a "0" configures the XRT83VL38 to operate in Dual-rail mode.	R/W	0
D6	ATAOS	Automatic Transmit All Ones Upon RLOS: Writing a "1" to this bit enables the automatic transmission of All "Ones" data to the line for the channel that detects an RLOS condition. Writing a "0" disables this feature.	R/W	0
D5	RCLKE	Receive Clock Edge: Writing a "1" to this bit selects receive output data of all channels to be updated on the negative edge of RCLK. Writing a "0" selects data to be updated on the positive edge of RCLK.	R/W	0
D4	TCLKE	Transmit Clock Edge: Writing a "0" to this bit selects transmit data at TPOS_n/TDATA_n and TNEG_n/CODES_n of all channels to be sampled on the falling edge of TCLK_n. Writing a "1" selects the rising edge of the TCLK_n for sampling.	R/W	0
D3	DATAP	DATA Polarity: Writing a "0" to this bit selects transmit input and receive output data of all channels to be active "High". Writing a "1" selects an active "Low" state.	R/W	0
D2	Reserved			0
D1	GIE	Global Interrupt Enable: Writing a "1" to this bit globally enables interrupt generation for all channels. Writing a "0" disables interrupt generation.	R/W	0
D0	SRESET	Software Reset μP Registers: Writing a "1" to this bit longer than 10 μ s initiates a device reset through the microprocessor interface. All internal circuits are placed in the reset state with this bit set to a "1" except the microprocessor register bits.	R/W	0

CLOCK SELECT REGISTER

The input clock source is used to generate all the necessary clock references internally to the LIU. The microprocessor timing is derived from a PLL output which is chosen by programming the Clock Select Bits and the Master Clock Rate in register 0x81h. Therefore, if the clock selection bits or the MCLRATE bit are being programmed, the frequency of the PLL output will be adjusted accordingly. During this adjustment, it is important to "Not" write to any other bit location within the same register while selecting the input/output clock frequency. For best results, register 0x81h can be broken down into two sub-registers with the MSB being bits D[7:3] and the LSB being bits D[2:0] as shown in **Figure 31**. Note: Bit D[7] is a reserved bit.

FIGURE 31. REGISTER 0X81H SUB REGISTERS

Programming Examples:

Example 1: Changing bits D[7:3]

If bits D[7:3] are the only values within the register that will change in a WRITE process, the microprocessor only needs to initiate ONE write operation.

Example 2: Changing bits D[2:0]

If bits D[2:0] are the only values within the register that will change in a WRITE process, the microprocessor only needs to initiate ONE write operation.

Example 3: Changing bits within the MSB and LSB

In this scenario, one must initiate TWO write operations such that the MSB and LSB do not change within ONE write cycle. It is recommended that the MSB and LSB be treated as two independent sub-registers. One can either change the clock selection (MSB) and then change bits D[2:0] (LSB) on the SECOND write, or vice-versa. No order or sequence is necessary.

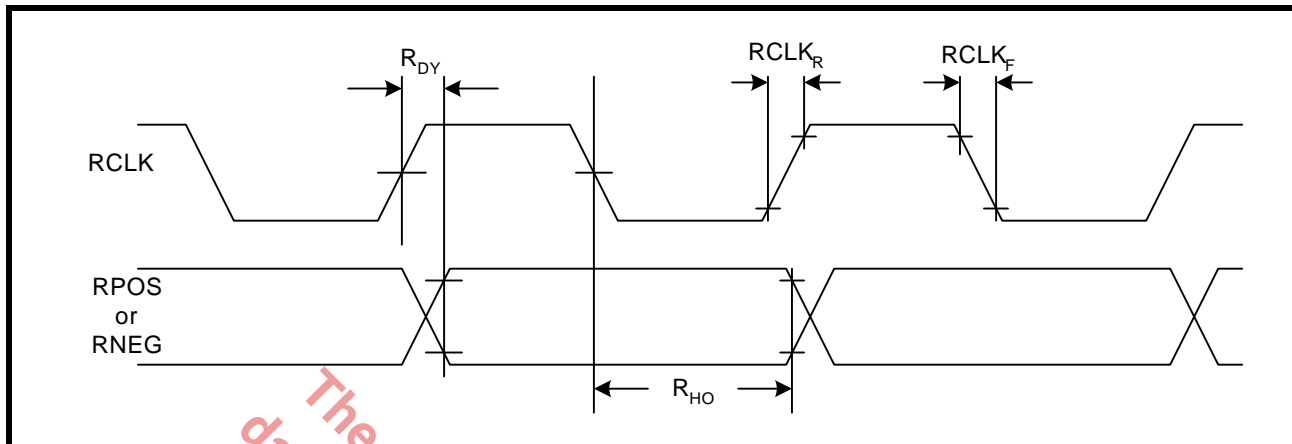

FIGURE 36. RECEIVE CLOCK AND OUTPUT DATA TIMING

MICROPROCESSOR INTERFACE I/O TIMING

INTEL INTERFACE TIMING - ASYNCHRONOUS

The signals used for the Intel microprocessor interface are: Address Latch Enable (ALE), Read Enable (\overline{RD}), Write Enable (WR), Chip Select (CS), Address and Data bits. The microprocessor interface uses minimum external glue logic and is compatible with the timings of the 8051 or 80C188 with an 8-16 MHz clock frequency, and with the timings of x86 or i960 family or microprocessors. The interface timing shown in Figure 37 and Figure 39 is described in Table 56.

t ₂	\overline{RD} Assert to \overline{RDY} Assert	-	135	ns
NA	\overline{RD} Pulse Width (t2)	135	-	ns
t ₃	\overline{CS} Falling Edge to \overline{WR} Assert	20	-	ns
t ₄	\overline{WR} Assert to \overline{RDY} Assert	-	135	ns
NA	\overline{WR} Pulse Width (t2)	135	-	ns
t ₅	\overline{CS} Falling Edge to AS Falling Edge	0	-	ns
Reset pulse width - both Motorola and Intel Operations (see Figure 39)				
t ₉	\overline{Reset} pulse width	10		μs

This product (or products) mentioned in this data sheet are no longer being manufactured and may not be ordered (OBS)

MOTOROLA ASYNCHRONOUS INTERFACE TIMING

The signals used in the Motorola microprocessor interface mode are: Address Strobe (AS), Data Strobe (\overline{DS}), Read/Write Enable ($\overline{R/W}$), Chip Select (\overline{CS}), Address and Data bits. The interface is compatible with the timing of a Motorola 68000 microprocessor family with up to 16.67 MHz clock frequency. The interface timing is shown in **Figure 38** and **Figure 39**. The I/O specifications are shown in **Table 57**.

FIGURE 38. MOTOROLA 68K ASYNCHRONOUS PROGRAMMED I/O INTERFACE TIMING

TABLE 57: ASYNCHRONOUS - MOTOROLA 68K - INTERFACE TIMING SPECIFICATION

SYMBOL	PARAMETER	MIN	MAX	UNITS
t_0	Valid Address to \overline{CS} Falling Edge	0	-	ns
t_1	\overline{CS} Falling Edge to \overline{DS} Assert	20	-	ns
t_2	\overline{DS} Assert to \overline{DTACK} Assert	-	135	ns
NA	\overline{DS} Pulse Width (t_2)	135	-	ns
t_3	\overline{CS} Falling Edge to \overline{AS} Falling Edge	0	-	ns
Reset pulse width - both Motorola and Intel Operations (see Figure 39)				
t_9	Reset pulse width	10	-	μ s

FIGURE 39. MICROPROCESSOR INTERFACE TIMING - RESET PULSE WIDTH

PACKAGE DIMENSIONS

225 BALL PLASTIC BALL GRID ARRAY (BOTTOM VIEW)
(19.0 X 19.0 X 1.0mm)

Note: The control dimension is in millimeter.

SYMBOL	INCHES		MILLIMETERS	
	MIN	MAX	MIN	MAX
A	0.049	0.096	1.24	2.45
A1	0.016	0.024	0.40	0.60
A2	0.013	0.024	0.32	0.60
A3	0.020	0.048	0.52	1.22
D	0.740	0.756	18.80	19.20
D1	0.669 BSC		17.00 BSC	
D2	0.665	0.669	16.90	17.00
b	0.020	0.028	0.50	0.70
e	0.039 BSC		1.00 BSC	

ORDERING INFORMATION

PART NUMBER	PACKAGE	OPERATING TEMPERATURE RANGE
XRT83VL38IB	225 Ball BGA	-40°C to +85°C

REVISIONS

REVISION #	DATE	DESCRIPTION
1.0.0	6/15/09	First Release of the Released Datasheet
1.0.1	8/27/10	Added missing pin definitions to the pin description table and updated micro-p documentation in functional description section.

The product (or products) mentioned in this data sheet are no longer being manufactured and may not be ordered (OBS)
